COMP9319 Web Data Compression and Search

Distributed path queries, Compressed inverted index

Intro to distributed query evaluation

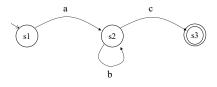

Web data is inherently distributed Reuse some techniques from distributed RDBMS if some schema info is known

New techniques required if no schema info is known

In XML, these links are denoted in XLinks and XPointers.

Example query

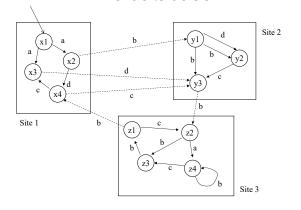

Assume data are distributed in 3 sites Assume the RPE: a.b*.c Assume the query starts from Site 1

Regular path expressions

Regular expressions for path, e.g.: a.b*.c a.b+.c

The database

Naïve approach

A naïve approach takes too many communication steps

=> we have to do more work locally

A better approach needs to

- 1. identify all external references
- 2. identify targets of external references

Input and output nodes

Site 1

Inputs: x1 (root), x4 Outputs: y1, y3

Site 2

Inputs: y1, y3 Outputs: z2

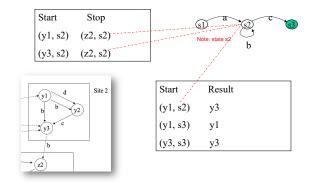

Site 3

Inputs: z2 Outputs: x4

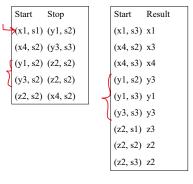

Query Processing

Given a query, we compute its automaton
Send it to each site
Start an identical process at each site
Compute two sets Stop(n, s) and Result(n, s)
Transmits the relations to a central location
and get their union

Stop and Result at site 2

Union the relations from all sites

The result of the query is $\{y3, z2, x3\}$

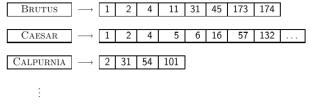

COMP9319: Web Data Compression and Search

Inverted index revisit & its compression

Slides modified from Hinrich Schütze and Christina Lioma slides on IIR

Inverted Index

For each term t, we store a list of all documents that contain t.

dictionary postings

Inverted index construction

Collect the documents to be indexed:

Friends, Romans, countrymen. So let it be with Caesar

2 Tokenize the text, turning each document into a list of tokens:

Friends Romans countrymen So . . .

3 Do linguistic preprocessing, producing a list of normalized tokens, which are the indexing terms: friend roman

countryman so

4 Index the documents that each term occurs in by creating an inverted index, consisting of a dictionary and postings.

Tokenizing and preprocessing

Doc 1. I did enact Julius Caesar: I was killed i' the Capitol; Brutus killed

Doc 2. So let it be with Caesar. The noble Brutus hath told you Caesar was ambitious:

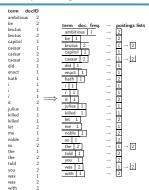

Doc 1. i did enact julius caesar i was killed i' the capitol brutus killed me Doc 2. so let it be with caesar the noble brutus hath told you caesar was

Generate posting

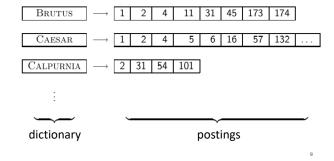

Sort postings

Create postings lists, determine document frequency

Split the result into dictionary and postings file

Simple conjunctive query (two terms)

- Consider the query: BRUTUS AND CALPURNIA
- To find all matching documents using inverted index:
 - 1 Locate BRUTUS in the dictionary
 - 2 Retrieve its postings list from the postings file
 - 3 Locate CALPURNIA in the dictionary
 - 4 Retrieve its postings list from the postings file
 - Intersect the two postings lists
 - 6 Return intersection to user

Intersecting two posting lists

Brutus \longrightarrow 1 \longrightarrow 2 \longrightarrow 45 \longrightarrow 173 \longrightarrow 174

Calpurnia \longrightarrow 2 \longrightarrow 31 \longrightarrow 54 \longrightarrow 101

Intersection \Longrightarrow 2 \longrightarrow 31

- This is linear in the length of the postings lists.
- Note: This only works if postings lists are sorted.

11

Intersecting two posting lists

```
Intersect(p_1, p_2)
  1 answer \leftarrow \langle \rangle
       while p_1 \neq \text{NIL} and p_2 \neq \text{NIL}
     do if docID(p_1) = docID(p_2)
  4
               then Add(answer, doclD(p_1))
  5
                      p_1 \leftarrow next(p_1)
                       p_2 \leftarrow next(p_2)
  6
  7
               else if doclD(p_1) < doclD(p_2)
  8
                         then p_1 \leftarrow next(p_1)
else p_2 \leftarrow next(p_2)
  g
 10 return answer
```

Typical query optimization

- Example query: BRUTUS AND CALPURNIA AND CAESAR
- Simple and effective optimization: Process in order of increasing frequency
- Start with the shortest postings list, then keep cutting further
- In this example, first CAESAR, then CALPURNIA, then BRUTUS

```
BRUTUS \longrightarrow \boxed{1} \longrightarrow 2 \longrightarrow 4 \longrightarrow 173 \longrightarrow 174

CALPURNIA \longrightarrow \boxed{2} \longrightarrow 31 \longrightarrow 54 \longrightarrow 101

CAESAR \longrightarrow \boxed{5} \longrightarrow 31
```

13

Optimized intersection algorithm for conjunctive queries

```
INTERSECT(\langle t_1, \dots, t_n \rangle)

1    terms \leftarrow SORTBYINCREASINGFREQUENCY(\langle t_1, \dots, t_n \rangle)

2    result \leftarrow postings(first(terms))

3    terms \leftarrow rest(terms)

4    while terms \neq NIL and result \neq NIL

5    do result \leftarrow INTERSECT(result, postings(first(terms)))

6    terms \leftarrow rest(terms)

7    return result
```

Recall basic intersection algorithm

Brutus \longrightarrow 1 \longrightarrow 2 \longrightarrow 45 \longrightarrow 173 \longrightarrow 174

Calpurnia \longrightarrow 2 \longrightarrow 31 \longrightarrow 45 \longrightarrow 101

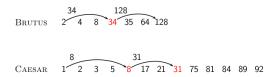

Intersection \Longrightarrow 2 \longrightarrow 31

- Linear in the length of the postings lists.
- Can we do better?

Skip pointers

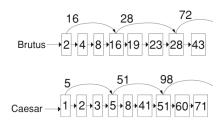

- Skip pointers allow us to skip postings that will not figure in the search results.
- This makes intersecting postings lists more efficient.
- Some postings lists contain several million entries so efficiency can be an issue even if basic intersection is linear.
- Where do we put skip pointers?
- How do we make sure intersection results are correct?

Basic idea

17

Skip lists: Larger example

18

Intersection with skip pointers

```
\begin{split} & \text{INTERSECTWITHSKIPS}(p_1, p_2) \\ & 1 \quad \textit{answer} \leftarrow \langle \; \rangle \\ & 2 \quad \text{while } p_1 \neq \text{NIL and } p_2 \neq \text{NIL} \\ & 3 \quad \text{do if } \textit{docID}(p_1) = \textit{docID}(p_2) \\ & 4 \quad \text{then } \text{ADD}(\textit{answer, } \textit{docID}(p_1)) \\ & 5 \quad p_1 - \textit{next}(p_2) \\ & 6 \quad p_2 - \textit{next}(p_2) \\ & 7 \quad \text{else if } \textit{docID}(p_1) < \textit{docID}(p_2) \\ & 8 \quad \text{then if } \textit{hasSkip}(p_1) \textit{ and } (\textit{docID}(\textit{skip}(p_1)) \leq \textit{docID}(p_2)) \\ & 9 \quad \text{then while } \textit{hasSkip}(p_1) \textit{ and } (\textit{docID}(\textit{skip}(p_1)) \leq \textit{docID}(p_2)) \\ & 10 \quad \textit{do } p_1 \leftarrow \textit{skip}(p_1) \\ & 11 \quad \text{else } p_1 \leftarrow \textit{next}(p_1) \\ & 12 \quad \text{else if } \textit{hasSkip}(p_2) \textit{ and } (\textit{docID}(\textit{skip}(p_2)) \leq \textit{docID}(p_1)) \\ & 13 \quad \text{then while } \textit{hasSkip}(p_2) \textit{ and } (\textit{docID}(\textit{skip}(p_2)) \leq \textit{docID}(p_1)) \\ & 14 \quad \textit{do } p_2 \leftarrow \textit{skip}(p_2) \\ & 15 \quad \text{else } p_2 \leftarrow \textit{next}(p_2) \\ & 16 \quad \text{return } \textit{answer} \\ \end{split}
```

19

Where do we place skips?

- Tradeoff: number of items skipped vs. frequency skip can be taken
- More skips: Each skip pointer skips only a few items, but we can frequently use it.
- Fewer skips: Each skip pointer skips many items, but we can not use it very often.

Phrase queries

- We want to answer a query such as [stanford university] as a phrase.
- Thus The inventor Stanford Ovshinsky never went to university should not be a match.
- The concept of phrase query has proven easily understood by users.
- About 10% of web queries are phrase queries.
- Consequence for inverted index: it no longer suffices to store docIDs in postings lists.
- Two ways of extending the inverted index:
 - biword index (cf. COMP6714)
 - positional index

Positional indexes

- Postings lists in a nonpositional index: each posting is just a docID
- Postings lists in a positional index: each posting is a docID and a list of positions

Positional indexes: Example

```
Query: "to<sub>1</sub> be<sub>2</sub> or<sub>3</sub> not<sub>4</sub> to<sub>5</sub> be<sub>6</sub>"

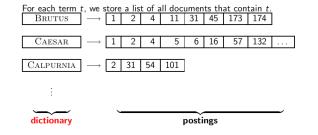

TO, 993427:

(1: <7, 18, 33, 72, 86, 231);
2: <1, 17, 74, 222, 255);
4: <8, 16, 190, 429, 433);
5: <363, 367);
7: <13, 23, 191); ... >

BE, 178239:
(1: <17, 25);
4: <17, 191, 291, 430, 434);
5: <14, 19, 101); ... > Document 4 is a match!
```

23

Inverted index

24

Dictionaries

- The dictionary is the data structure for storing the term vocabulary.
- Term vocabulary: the data
- Dictionary: the data structure for storing the term vocabulary

25

Dictionary as array of fixed-width entries

- For each term, we need to store a couple of items:
 - document frequency
 - pointer to postings list
 - . . .
- Assume for the time being that we can store this information in a fixed-length entry.
- Assume that we store these entries in an array.

Dictionary as array of fixed-width entries

term	document	pointer to
	frequency	postings list
а	656,265	\longrightarrow
aachen	65	\longrightarrow
zulu	221	─

space needed: 20 bytes 4 bytes 4 bytes

How do we look up a query term q_i in this array at query time? That is: which data structure do we use to locate the entry (row) in the array where q_i is stored?

26

Data structures for looking up term

- Two main classes of data structures: hashes and trees
- Some IR systems use hashes, some use trees.
- Criteria for when to use hashes vs. trees:
 - Is there a fixed number of terms or will it keep growing?
 - What are the relative frequencies with which various keys will be accessed?
 - How many terms are we likely to have?

Hashes

- Each vocabulary term is hashed into an integer.
- Try to avoid collisions
- At query time, do the following: hash query term, resolve collisions, locate entry in fixed-width array
- Pros: Lookup in a hash is faster than lookup in a tree.
 - Lookup time is constant.
- Cons
 - no way to find minor variants (resume vs. résumé)
 - no prefix search (all terms starting with automat)
 - need to rehash everything periodically if vocabulary keeps growing

29

Trees

- Trees solve the prefix problem (find all terms starting with automat).
- Simplest tree: binary tree
- Search is slightly slower than in hashes: $O(\log M)$, where M is the size of the vocabulary.
- O(logM) only holds for balanced trees.
- Rebalancing binary trees is expensive.
- B-trees mitigate the rebalancing problem.
- B-tree definition: every internal node has a number of children in the interval [a, b] where a, b are appropriate positive integers, e.g., [2, 4].

30

Sort-based index construction

- As we build index, we parse docs one at a time.
- The final postings for any term are incomplete until the end.
- Can we keep all postings in memory and then do the sort inmemory at the end?
- No, not for large collections
- At 10–12 bytes per postings entry, we need a lot of space for large collections.
- But in-memory index construction does not scale for large collections.
- Thus: We need to store intermediate results on disk.

31

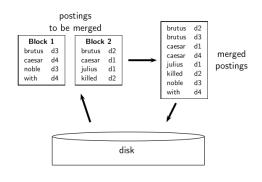

Same algorithm for disk?

- Can we use the same index construction algorithm for larger collections, but by using disk instead of memory?
- No: Sorting for example 100,000,000 records on disk is too slow – too many disk seeks.
- We need an external sorting algorithm.

"External" sorting algorithm (using few disk seeks)

- We must sort 100,000,000 non-positional postings.
 - Each posting has size 12 bytes (4+4+4: termID, docID, document frequency).
- Define a block to consist of 10,000,000 such postings
 - We can easily fit that many postings into memory.
 - We will have 10 such blocks.
- Basic idea of algorithm:
 - For each block: (i) accumulate postings, (ii) sort in memory, (iii) write to disk
 - Then merge the blocks into one long sorted order.

Merging two blocks

Why compression in information retrieval?

- First, we will consider space for dictionary
 - Main motivation for dictionary compression: make it small enough to keep in main memory
- Then for the postings file
 - Motivation: reduce disk space needed, decrease time needed to read from disk
 - Note: Large search engines keep significant part of postings in
- We will devise various compression schemes for dictionary and postings.

Dictionary compression

- The dictionary is small compared to the postings file.
- But we want to keep it in memory.
- Also: competition with other applications, cell phones, onboard computers, fast startup time
- So compressing the dictionary is important.

Recall: Dictionary as array of fixed-width entries

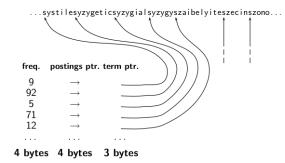

term	document	pointer to
	frequency	postings list
a	656,265	\longrightarrow
aachen	65	\longrightarrow
zulu	221	\longrightarrow

Space needed: 20 bytes 4 bytes 4 bytes for Reuters: (20+4+4)*400,000 = 11.2 MB

Fixed-width entries are bad.

- Most of the bytes in the term column are wasted.
 - We allot 20 bytes for terms of length 1.
- We can't handle HYDROCHLOROFLUOROCARBONS and SUPERCALIFRAGILISTICEXPIALIDOCIOUS
- Average length of a term in English: 8 characters
- How can we use on average 8 characters per term?

Dictionary as a string

Space for dictionary as a string

- 4 bytes per term for frequency
- 4 bytes per term for pointer to postings list
- 8 bytes (on average) for term in string
- 3 bytes per pointer into string (need log₂ 8 · 400000 < 24 bits to resolve 8 · 400,000 positions)
- Space: 400,000 × (4 +4 +3 +8) = 7.6MB (compared to 11.2 MB for fixed-width array)

Dictionary as a string with blocking

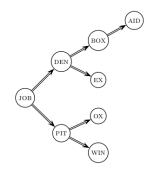

40

Space for dictionary as a string with blocking

- Example block size k = 4
- Where we used 4 × 3 bytes for term pointers without blocking . . .
- ...we now use 3 bytes for one pointer plus 4 bytes for indicating the length of each term.
- We save 12 (3 + 4) = 5 bytes per block.
- Total savings: 400,000/4 * 5 = 0.5 MB
- This reduces the size of the dictionary from 7.6 MB to 7.1

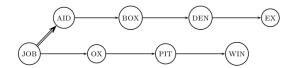

42

Lookup of a term without blocking

43

Lookup of a term with blocking: (slightly) slower

Front coding

One block in blocked compression (k=4) . . . 8 a u t o m a t a 8 a u t o m a t e 9 a u t o m a t i c 10 a u t o m a t i o n

... further compressed with front coding. 8 a u t o m a t * a 1 * e 2 * i c 3 * i o n

Dictionary compression for Reuters: Summary

data structure	size in MB
dictionary, fixed-width	11.2
dictionary, term pointers into string	7.6
\sim , with blocking, k = 4	7.1
~, with blocking & front coding	5.9

Postings compression

- The postings file is much larger than the dictionary, factor of at least 10.
- Key desideratum: store each posting compactly
- A posting for our purposes is a docID.
- For Reuters (800,000 documents), we would use 32 bits per docID when using 4-byte integers.
- Alternatively, we can use log₂ 800,000 ≈ 19.6 < 20 bits per docID.
- Our goal: use a lot less than 20 bits per docID.

47

Key idea: Store gaps instead of docIDs

- Each postings list is ordered in increasing order of docID.
- Example postings list: COMPUTER: 283154, 283159, 283202, . . .
- It suffices to store gaps: 283159-283154=5, 283202-283154=43
- Example postings list using gaps: COMPUTER: 283154, 5, 43, . . .
- Gaps for frequent terms are small.
- Thus: We can encode small gaps with fewer than 20 bits.

Gap encoding

	encoaing	postings	IIST								
THE	docIDs			283042		283043		283044		283045	
	gaps				1		1		1		
COMPUTER	docIDs			283047		283154		283159		283202	
	gaps				107		5		43		
ARACHNOCENTRIC	docIDs	252000		500100							
	gans	252000	248100								

4

Variable length encoding

- Aim:
 - For ARACHNOCENTRIC and other rare terms, we will use about 20 bits per gap (= posting).
 - For THE and other very frequent terms, we will use only a few bits per gap (= posting).
- In order to implement this, we need to devise some form of variable length encoding.
- Variable length encoding uses few bits for small gaps and many bits for large gaps.

Variable byte (VB) code

- Used by many commercial/research systems
- Good low-tech blend of variable-length coding and sensitivity to alignment matches (bit-level codes, see later).
- Dedicate 1 bit (high bit) to be a continuation bit c.
- If the gap G fits within 7 bits, binary-encode it in the 7 available bits and set c = 1.
- Else: encode lower-order 7 bits and then use one or more additional bytes to encode the higher order bits using the same algorithm.
- At the end set the continuation bit of the last byte to 1 (c = 1) and of the other bytes to 0 (c = 0).

VB code examples

```
        docIDs
        824
        829
        215406

        gaps
        5
        214577

        VB code
        00000110 10111000
        10000101
        00001101 00001100 10110001
```

VB code encoding algorithm

8 return bytes

VB code decoding algorithm

```
 \begin{array}{ll} \text{VBDecode}(\textit{bytestream}) \\ 1 & \textit{numbers} \leftarrow \langle \rangle \\ 2 & \textit{n} \leftarrow 0 \\ 3 & \textbf{for } i \leftarrow 1 \textbf{ to } \text{Length}(\textit{bytestream}) \\ 4 & \textbf{do if } \textit{bytestream}[i] < 128 \\ 5 & \textbf{then } n \leftarrow 128 \times n + \textit{bytestream}[i] \\ 6 & \textbf{else } n \leftarrow 128 \times n + (\textit{bytestream}[i] - 128) \\ 7 & \text{Append}(\textit{numbers}, n) \\ 8 & \textit{n} \leftarrow 0 \\ 9 & \textbf{return } \textit{numbers} \end{array}
```

54

Gamma codes for gap encoding

- You can get even more compression with another type of variable length encoding: bitlevel code.
- Gamma code is the best known of these.
- First, we need unary code to be able to introduce gamma code.
- Unary code
 - Represent *n* as *n* 1s with a final 0.
 - Unary code for 3 is 1110
 - Unary code for 40 is

 - Unary code for 70 is:

5

Gamma code

- Represent a gap G as a pair of length and offset.
- Offset is the gap in binary, with the leading bit chopped off.
- For example 13 \rightarrow 1101 \rightarrow 101 = offset
- Length is the length of offset.
- For 13 (offset 101), the length is 3.
- Encode length in unary code: 1110.
- Gamma code of 13 is the concatenation of length and offset: 1110101.

Gamma code examples

number	unary code	length	offset	γ code
0	0			_
1	10	0		0
2	110	10	0	10,0
3	1110	10	1	10,1
4	11110	110	00	110,00
9	1111111110	1110	001	1110,001
13		1110	101	1110,101
24		11110	1000	11110,1000
511		111111110	11111111	111111110,11111111
1025		11111111110	0000000001	11111111110.00000000001

Properties of gamma code

- Gamma code is prefix-free
- The length of offset is [log₂ G] bits.
- The length of length is $[\log_2 G] + 1$ bits,
- So the length of the entire code is 2 x [log₂ G] + 1 bits.
- Υ codes are always of odd length.
- Gamma codes are within a factor of 2 of the optimal encoding length log₂ G.

Gamma codes: Alignment

- Machines have word boundaries 8, 16, 32 bits
- Compressing and manipulating at granularity of bits can be slow.
- Variable byte encoding is aligned and thus potentially more officient
- Regardless of efficiency, variable byte is conceptually simpler at little additional space cost.

Compression of Reuters

data structure	size in MB
dictionary, fixed-width	11.2
dictionary, term pointers into string	7.6
~, with blocking, k = 4	7.1
~, with blocking & front coding	5.9
collection (text, xml markup etc)	3600.0
collection (text)	960.0
T/D incidence matrix	40,000.0
postings, uncompressed (32-bit words)	400.0
postings, uncompressed (20 bits)	250.0
postings, variable byte encoded	116.0
postings, gamma encoded	101.0

60
